In underburned brick the presence of untransformed quartz may also cause a slight volume increase at 575 C on heating. It is between atmospheric temperature and 3000 C that practically all spalling takes place. The measurement of these volume changes below 3000 C offers an interesting problem for future work, as does also the development of a spalling test. Some work has been contemplated on the measurement of these tridymite and cristobalite expansions in commercial silica brick. It should, if conducted with moderate accuracy, be a fair guide to the amounts of tridymite and cristobalite contained by the samples under test. Incidentally, it would show how the exterior volume expansions at these temperatures vary with the different brands...
